Inheritance in Python

Difficulty Level : Easy • Last Updated : 21 Nov, 2022

One of the core concepts in object-oriented programming (OOP) languages is inheritance. It is a mechanism that allows you to create a hierarchy of classes that share a set of properties and methods by deriving a class from another class. Inheritance is the capability of one class to derive or inherit the properties from another class.

Benefits of inheritance are:

- It represents real-world relationships well.
- It provides the **reusability** of a code. We don't have to write the same code again and again. Also, it allows us to add more features to a class without modifying it.
- It is transitive in nature, which means that if class B inherits from another class A, then all the subclasses of B would automatically inherit from class A.
- Inheritance offers a simple, understandable model structure.
- Less development and maintenance expenses result from an inheritance.

Python Inheritance Syntax

```
Class BaseClass:  
    {Body}  
  
Class DerivedClass(BaseClass):  
    {Body}
```

Creating a Parent Class

Creating a **Person class** with **Display methods**.

```
# A Python program to demonstrate inheritance
```

[Read](#)[Discuss](#)[Courses](#)[Practice](#)[Video](#)

```
# Constructor
```

```
def __init__(self, name, id):  
    self.name = name  
    self.id = id
```

```
# To check if this person is an employee
```

```
def Display(self):  
    print(self.name, self.id)
```

```
# Driver code
```

```
emp = Person("Satyam", 102) # An Object of Person  
emp.Display()
```

Output:

Satyam 102

Creating a Child Class

Here **Emp** is another class which is going to inherit the properties of the **Person** class(base class).

[Data Structures and Algorithms](#) [Interview Preparation](#) [Data Science](#) [Topic-wise Practice](#) [C](#) [Python](#)[Read](#) [Discuss](#) [Courses](#) [Practice](#) [Video](#)

```
print("Emp class called")
```

```
Emp_details = Emp("Mayank", 103)

# calling parent class function
Emp_details.Display()

# Calling child class function
Emp_details.Print()
```

Output:

```
Mayank 103
Emp class called
```

Example of Inheritance in Python

Python3

```
# A Python program to demonstrate inheritance

# Base or Super class. Note object in bracket.
# (Generally, object is made ancestor of all classes)
# In Python 3.x "class Person" is
# equivalent to "class Person(object)"
```

```
class Person(object):

    # Constructor
    def __init__(self, name):
        self.name = name

    # To get name
    def getName(self):
        return self.name

    # To check if this person is an employee
    def isEmployee(self):
```

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

Inherited or Subclass (Note Person in bracket)

[Read](#) [Discuss](#) [Courses](#) [Practice](#) [Video](#)

Here we return true

```
def isEmployee(self):
    return True
```

Driver code

```
emp = Person("Geek1") # An Object of Person
print(emp.getName(), emp.isEmployee())
```

```
emp = Employee("Geek2") # An Object of Employee
print(emp.getName(), emp.isEmployee())
```

Output:

```
Geek1 False
Geek2 True
```

What is object class?

Like the [Java Object class](#), in [Python](#) (from version 3. x), the object is the root of all classes.

- In Python 3.x, "class Test(object)" and "class Test" are same.
- In Python 2. x, "class Test(object)" creates a class with the object as a parent (called a new-style class), and "class Test" creates an old-style class (without an objecting parent).

Subclassing (Calling constructor of parent class)

A child class needs to identify which class is its parent class. This can be done by mentioning the parent class name in the definition of the child class.

Eg: class **subclass_name (superclass_name)**:

Python3

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

parent class

Read Discuss Courses Practice Video

__init__ is known as the constructor

```
def __init__(self, name, idnumber):
    self.name = name
    self.idnumber = idnumber
```

```
def display(self):
    print(self.name)
    print(self.idnumber)
```

child class

```
class Employee(Person):
    def __init__(self, name, idnumber, salary, post):
        self.salary = salary
        self.post = post
```

invoking the __init__ of the parent class
 Person.__init__(self, name, idnumber)

creation of an object variable or an instance

```
a = Employee('Rahul', 886012, 200000, "Intern")
```

calling a function of the class Person using its instance

```
a.display()
```

Output:

```
Rahul
886012
```

'a' is the instance created for the class Person. It invokes the `__init__()` of the referred class. You can see 'object' written in the declaration of the class Person. In Python, every class inherits from a built-in basic class called 'object'. The constructor i.e. the '`__init__`' function of a class is invoked when we create an object variable or an instance of the class.

The variables defined within `__init__()` are called the instance variables or objects.

Here, `name` and `idnumber` are the objects of the class Person. Similarly, `salary` and

'post' are the objects of the class Employee. Since the class Employee inherits from class

[Read](#)[Discuss](#)[Courses](#)[Practice](#)[Video](#)

Python program to demonstrate error if we forget to invoke `__init__()` of the parent

If you forget to invoke the `__init__()` of the parent class then its instance variables would not be available to the child class.

The following code produces an error for the same reason.

Python3

```
class A:
    def __init__(self, n='Rahul'):
        self.name = n
```

```
class B(A):
    def __init__(self, roll):
        self.roll = roll
```

```
object = B(23)
print(object.name)
```

Output :

Traceback (most recent call last):

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

```
print (object.name)
```

```
AttributeError: 'B' object has no attribute 'name'
```

[Read](#)[Discuss](#)[Courses](#)[Practice](#)[Video](#)

Different types of Inheritance:

- **Single inheritance:** When a child class inherits from only one parent class, it is called single inheritance. We saw an example above.
- **Multiple inheritances:** When a child class inherits from multiple parent classes, it is called multiple inheritances.

Unlike java, python shows multiple inheritances.

Python3

```
# Python example to show the working of multiple  
# inheritance
```

```
class Base1(object):  
    def __init__(self):  
        self.str1 = "Geek1"  
        print("Base1")
```

```
class Base2(object):  
    def __init__(self):  
        self.str2 = "Geek2"  
        print("Base2")
```

```
class Derived(Base1, Base2):  
    def __init__(self):  
  
        # Calling constructors of Base1  
        # and Base2 classes  
        Base1.__init__(self)  
        Base2.__init__(self)  
        print("Derived")  
  
    def printStrs(self):  
        print(self.str1, self.str2)
```

```
ob.printStrs()
```

[Read](#)[Discuss](#)[Courses](#)[Practice](#)[Video](#)

Base1

Base2

Derived

Geek1 Geek2

- **Multilevel inheritance:** When we have a child and grandchild relationship.

Python3

```
# A Python program to demonstrate inheritance
```

```
# Base or Super class. Note object in bracket.
```

```
# (Generally, object is made ancestor of all classes)
```

```
# In Python 3.x "class Person" is
```

```
# equivalent to "class Person(object)"
```

```
class Base(object):
```

```
    # Constructor
```

```
    def __init__(self, name):  
        self.name = name
```

```
    # To get name
```

```
    def getName(self):  
        return self.name
```

```
# Inherited or Sub class (Note Person in bracket)
```

```
class Child(Base):
```

```
    # Constructor
```

```
    def __init__(self, name, age):  
        Base.__init__(self, name)  
        self.age = age
```

```
    # To get name
```

```
    def getAge(self):  
        return self.age
```

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

[Read](#) [Discuss](#) [Courses](#) [Practice](#) [Video](#)

```
# Constructor
def __init__(self, name, age, address):
    Child.__init__(self, name, age)
    self.address = address

# To get address
def getAddress(self):
    return self.address

# Driver code
g = GrandChild("Geek1", 23, "Noida")
print(g.getName(), g.getAge(), g.getAddress())
```

Output:

Geek1 23 Noida

- **Hierarchical inheritance** More than one derived class are created from a single base.
- **Hybrid inheritance:** This form combines more than one form of inheritance. Basically, it is a blend of more than one type of inheritance.

For more details please read this article: [Types of inheritance in Python](#)

Private members of the parent class

We don't always want the instance variables of the parent class to be inherited by the child class i.e. we can make some of the instance variables of the parent class private, which won't be available to the child class.

We can make an instance variable private by adding double underscores before its name. For example,

Python3

```
# Python program to demonstrate private members
# of the parent class
```

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

```
class C(object):  
    def __init__(self):
```

[Read](#) [Discuss](#) [Courses](#) [Practice](#) [Video](#)

```
        # d is private instance variable  
        self.__d = 42
```

```
class D(C):  
    def __init__(self):  
        self.e = 84  
        C.__init__(self)
```

```
object1 = D()
```

```
# produces an error as d is private instance variable  
print(object1.d)
```

Output :

```
File "/home/993bb61c3e76cda5bb67bd9ea05956a1.py", line 16, in  
    print (object1.d)
```

```
AttributeError: type object 'D' has no attribute 'd'
```

Since 'd' is made private by those underscores, it is not available to the child class 'D' and hence the error.
